

NutrioBox Dispatch — System Architecture

v3.9.74 · scan-local / submit-once

How the gun, server and PACT connect today: orders & stock flow OUT of PACT to the gun; the operator scans locally on the device; on Submit the whole order is posted back into PACT as ONE Stock Outward voucher.

SUBMIT: the whole saved order goes INTO PACT → API queues one job; the worker logs in and types every line into ONE Stock Outward voucher

if a single very large voucher won't commit, it safely falls back to small batches — scans are never lost, nothing is dispatched twice

Read it as a loop. PACT (5) is the master. The worker robot (4) reads PACT's order & stock reports and writes them to the database (3); the API (2) serves those to the gun (1). The operator scans on the gun, and every scan is **saved locally on the device** (green) — nothing is sent anywhere until they press **Submit**. Submit puts one job in the queue; the worker logs into PACT and types the entire order into a single Stock Outward voucher (red), after checking what PACT has already delivered so nothing double-dispatches. **Blue = data out of PACT · Green = local scanning · Red = dispatch back in.**
